

A complex, stylized diagram in shades of red and black. It features a central cloud with a keyhole, a large upward-pointing arrow, a database cylinder, a server rack, and various geometric shapes like squares, circles, and lines, some with 'X' marks, suggesting a network or data flow architecture.

Cloud Native Landscape

l.cncf.io

This landscape is intended as a map through the previously uncharted terrain of cloud native technologies. There are many routes to deploying a cloud native application, with CNCF Projects representing a particularly well-traveled path.

An abstract graphic on the left side of the slide, rendered in various shades of red. It features a vertical stack of server racks at the bottom, a cloud with a keyhole icon, a database cylinder, and several curved arrows pointing upwards and outwards, suggesting a flow or process. There are also some 'x' and 'o' symbols scattered within the graphic.

OpenShift and Kubernetes core concepts

a container is the smallest compute unit

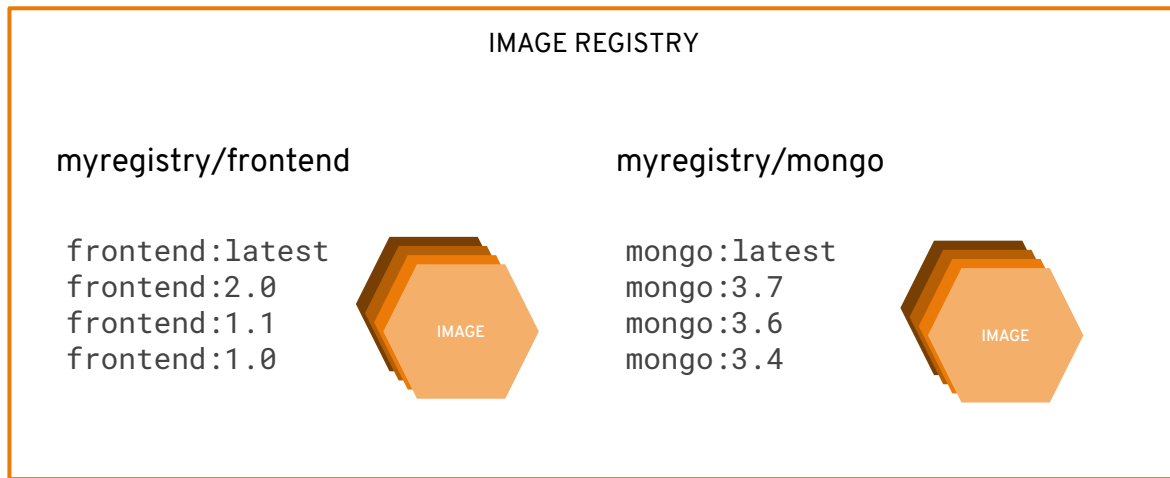

containers are created from container images

container images are stored in an image registry

an image repository contains all versions of an image in the image registry

containers are wrapped in pods which are units of deployment and management

10.140.4.44

10.15.6.55

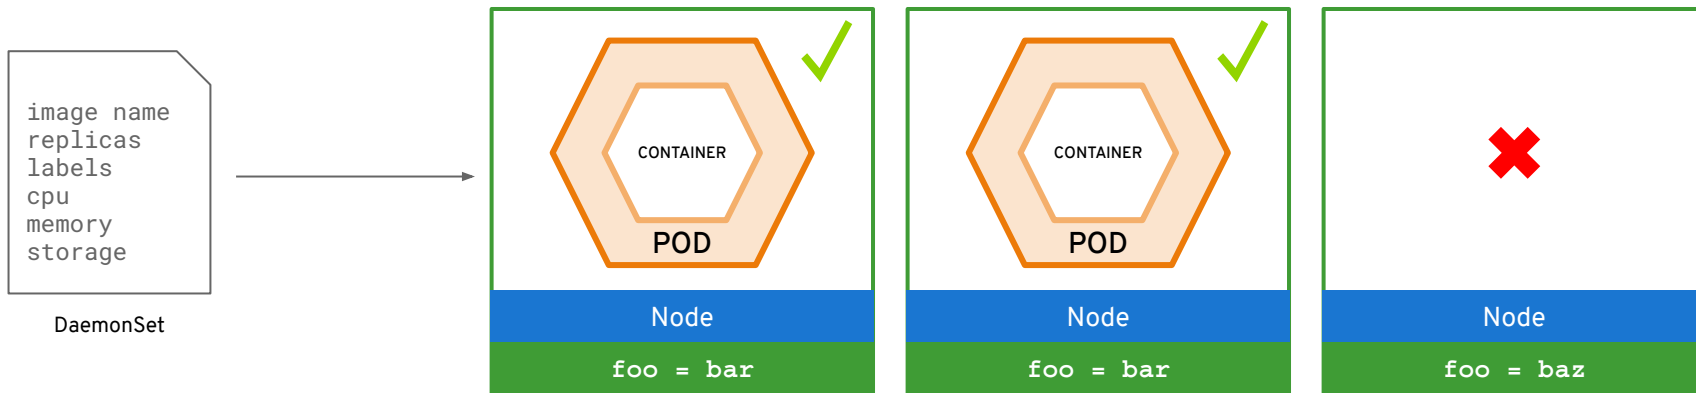

ReplicationControllers & ReplicaSets ensure a specified number of pods are running at any given time

Deployments and DeploymentConfigurations define how to roll out new versions of Pods

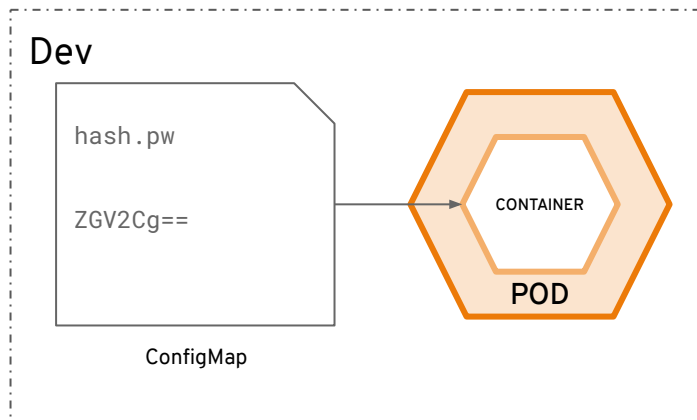

a daemonset ensures that all
(or some) nodes run a copy of a
pod

configmaps allow you to decouple configuration artifacts from image content

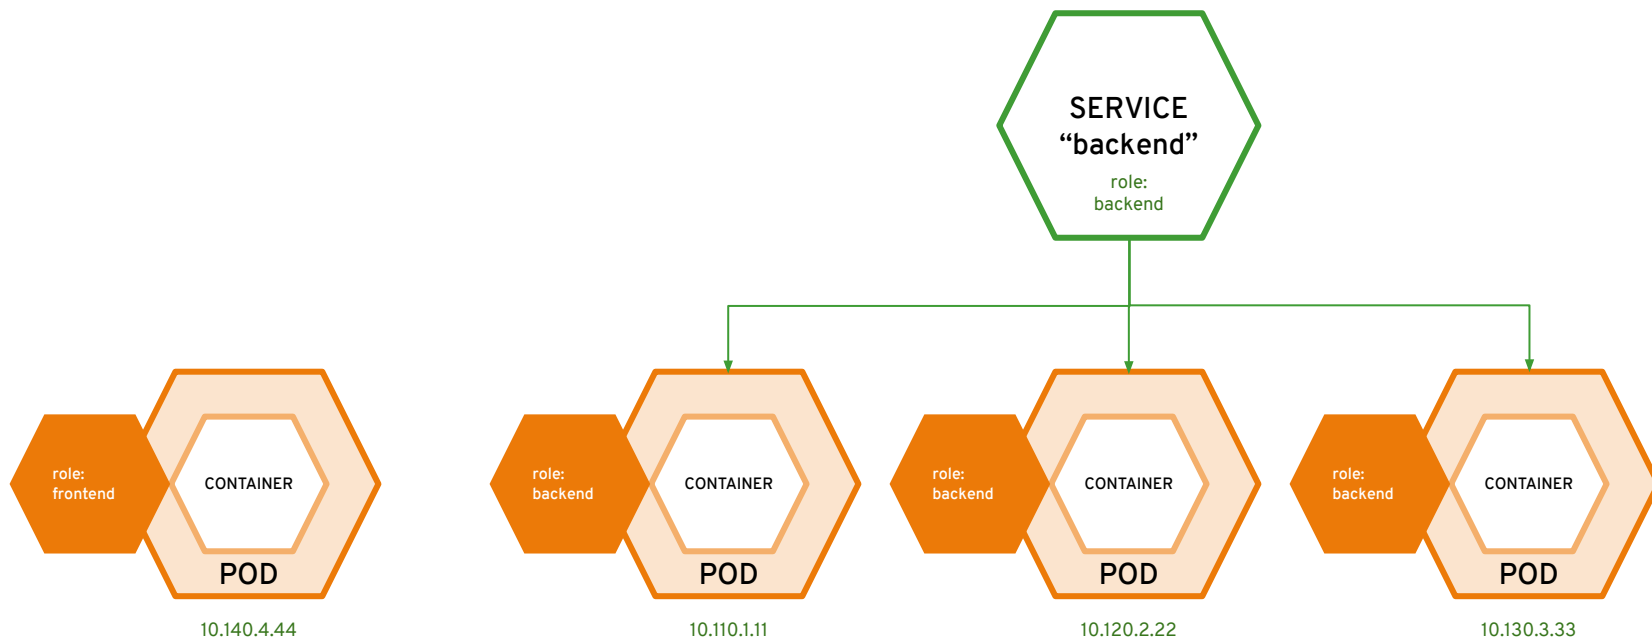

secrets provide a mechanism to hold sensitive information such as passwords

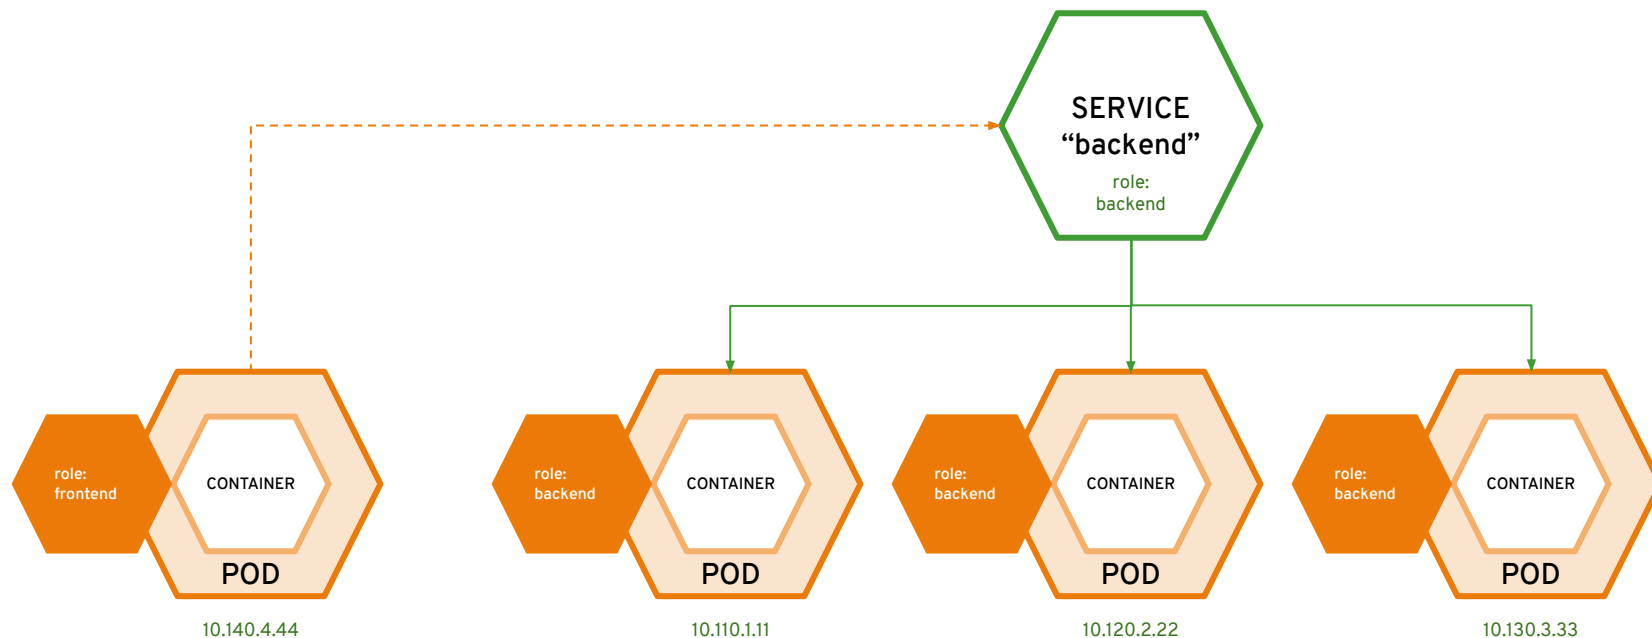

The etcd datastore can be encrypted for additional security

<https://docs.openshift.com/container-platform/4.6/security/encrypting-etcd.html>

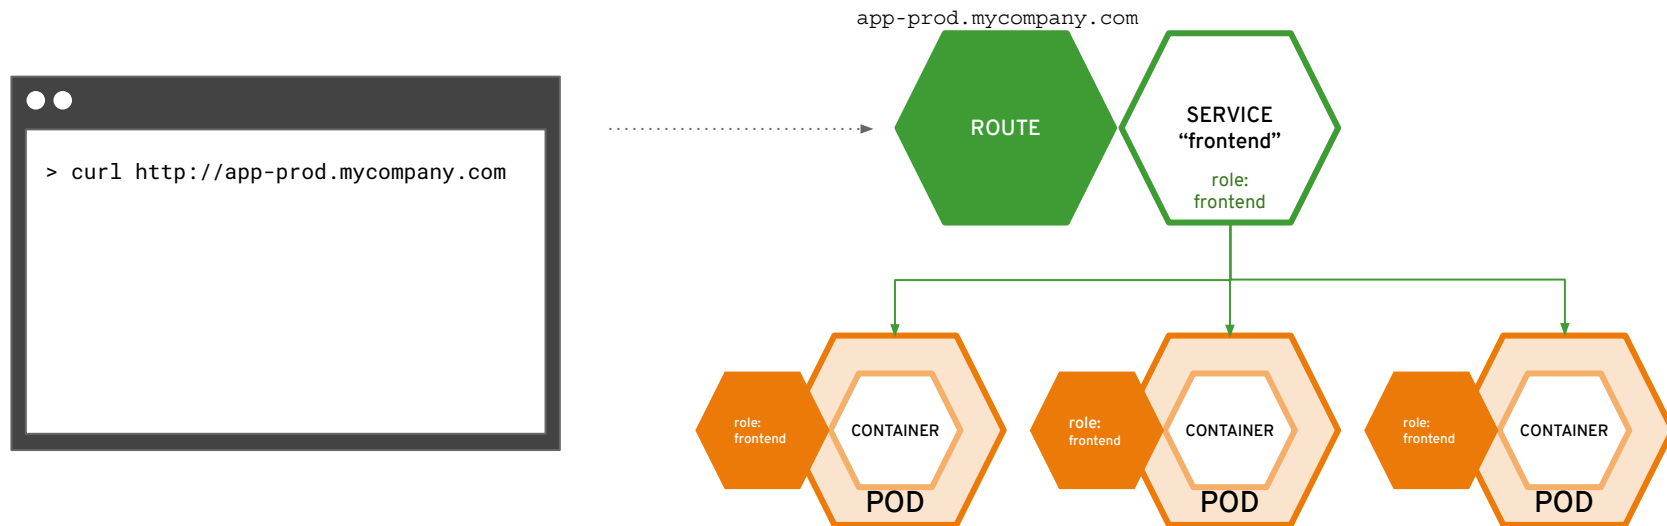

services provide internal load-balancing and service discovery across pods

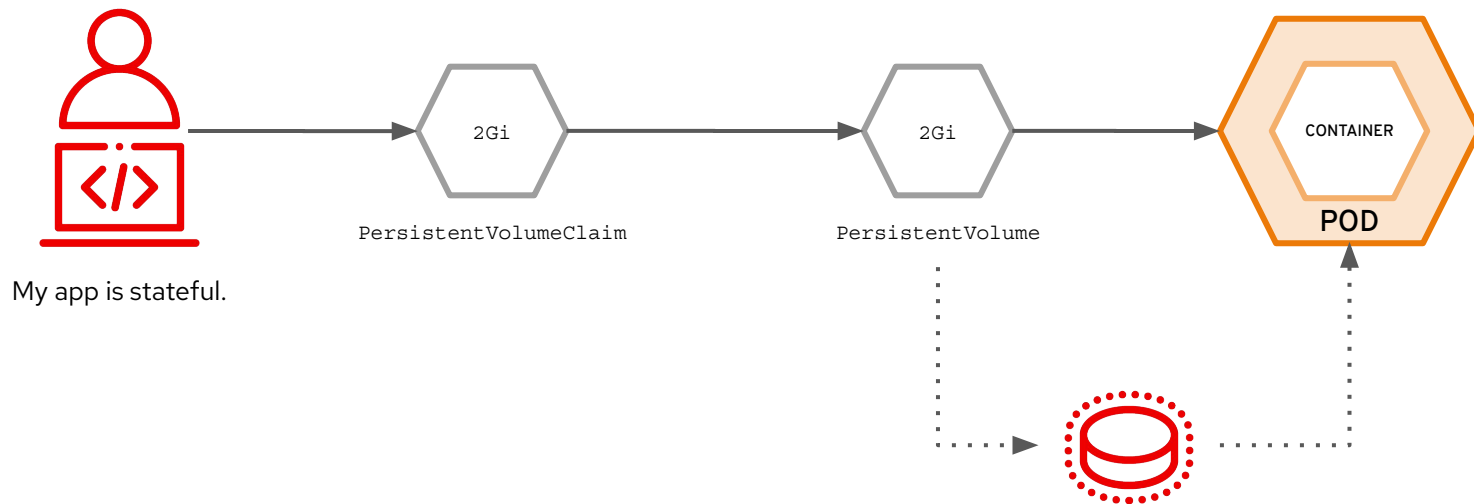

apps can talk to each other via services

routes make services accessible to clients outside the environment via real-world urls

Persistent Volume and Claims

Liveness and Readiness

projects isolate apps across environments, teams, groups and departments

OpenShift 4 Architecture

your choice of infrastructure

COMPUTE

NETWORK

STORAGE

workers run workloads

masters are the control plane

everything runs in pods

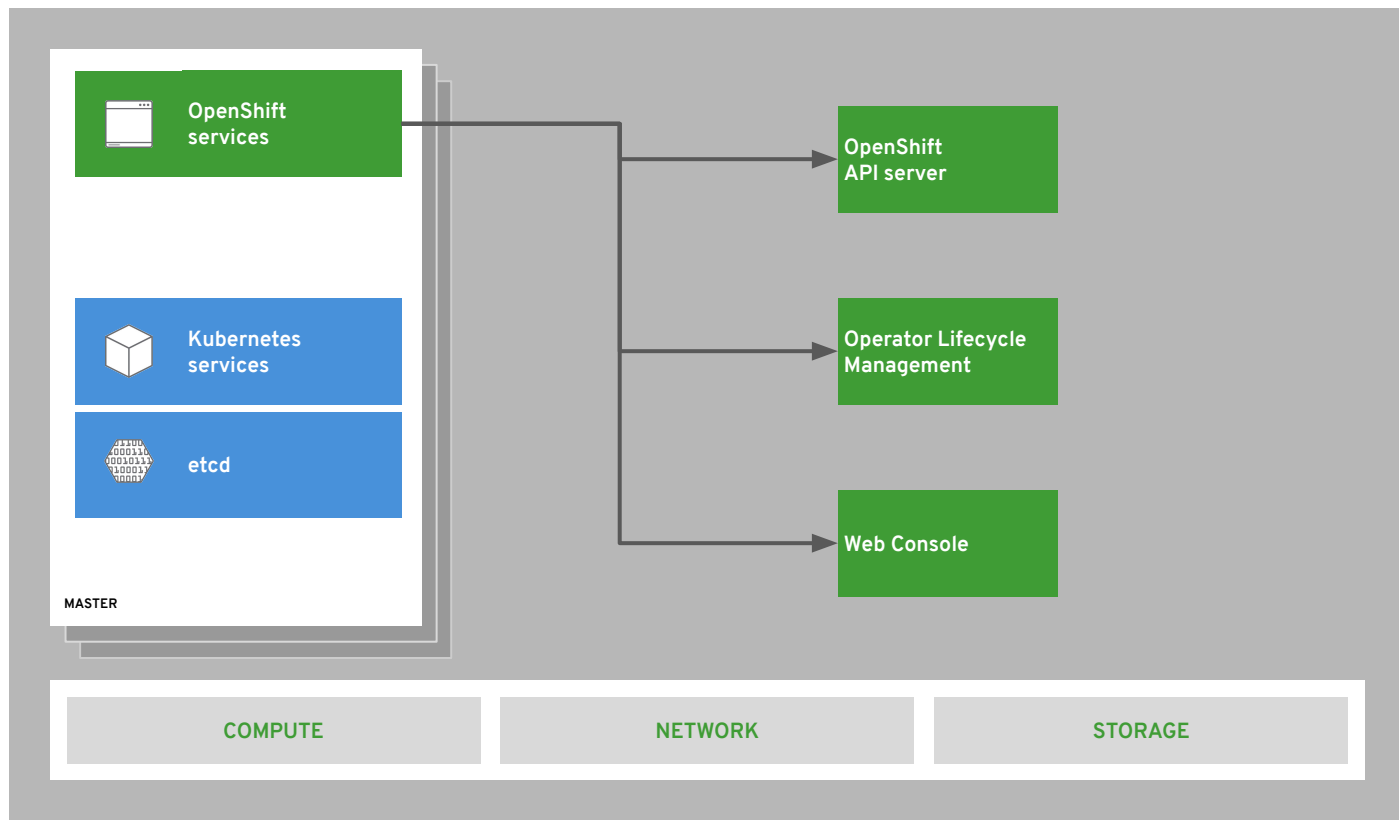

state of everything

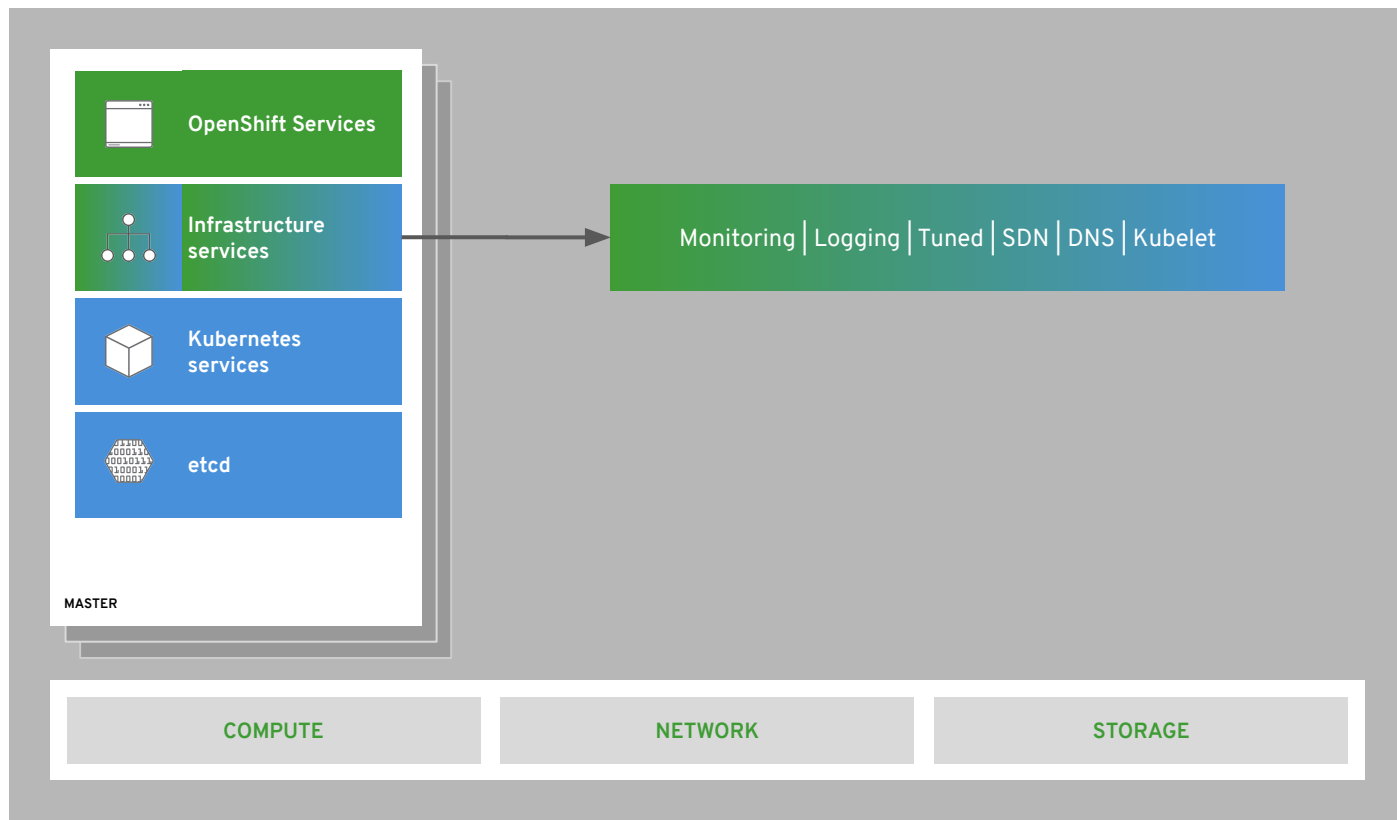

core kubernetes components

core OpenShift components

internal and support infrastructure services

run on all hosts

integrated image registry

cluster monitoring

log aggregation

integrated routing

dev and ops via web, cli, API, and IDE

Networking

A pluggable model for
network interface
controls in kubernetes

OpenShift Networking Plug-ins

3rd-party Kubernetes CNI plug-in certification primarily consists of:

1. Formalizing the partnership
2. Certifying the container(s)
3. Certifying the Operator
4. Successfully passing the same Kubernetes networking conformance tests that OpenShift uses to validate its own SDN

OpenShift SDN

An Open
vSwitch-based
Software Defined
Network for
kubernetes

OpenShift SDN high-level architecture

OpenShift SDN “flavors”

OPEN NETWORK (Default)

- All pods can communicate with each other across projects

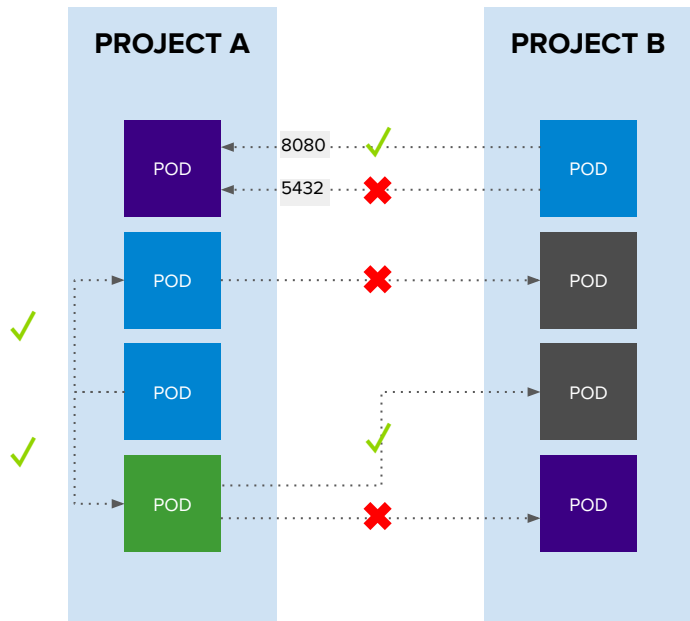

MULTI-TENANT NETWORK

- Project-level network isolation
- Multicast support
- Egress network policies

Multi-Tenant Network

NetworkPolicy

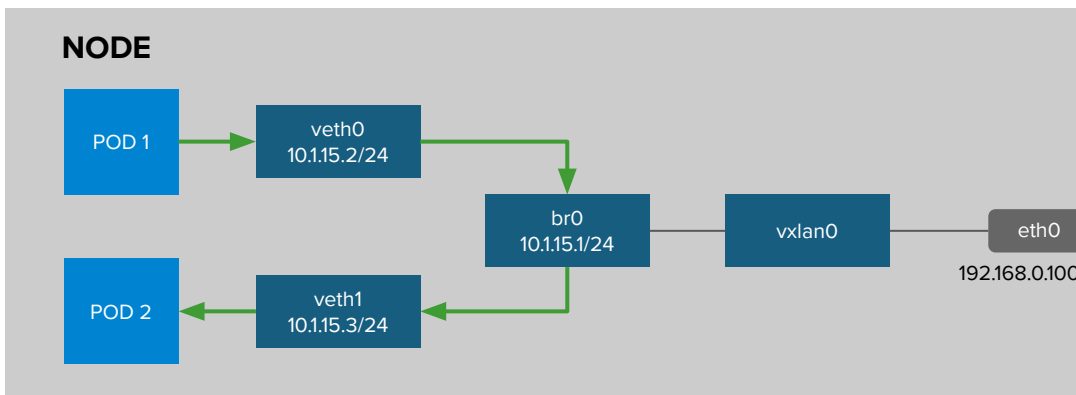

Example Policies

- Allow all traffic inside the project
- Allow traffic from green to gray
- Allow traffic to purple on 8080

```
apiVersion: extensions/v1beta1
kind: NetworkPolicy
metadata:
  name: allow-to-purple-on-8080
spec:
  podSelector:
    matchLabels:
      color: purple
  ingress:
    - ports:
      - protocol: tcp
        port: 8080
```

OpenShift SDN packet flows

container-container on same host

OpenShift SDN packet flows

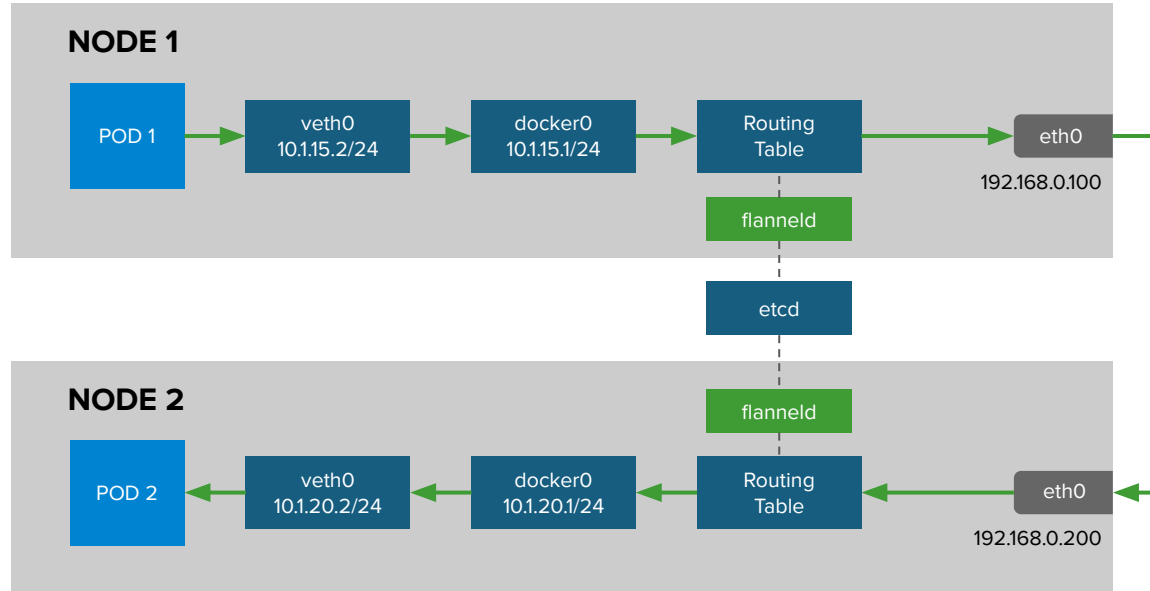

container-container across hosts

OpenShift SDN packet flows container leaving the host

Kuryr and OpenStack

Flannel is minimally verified and is supported only and exactly as deployed in the OpenShift on OpenStack reference architecture <https://access.redhat.com/articles/2743631>

routes and ingress

How traffic enters the
cluster

Routing and Load Balancing

- Pluggable routing architecture
 - HAProxy Router
 - F5 Router
- Multiple-routers with traffic sharding
- Router supported protocols
 - HTTP/HTTPS
 - WebSockets
 - TLS with SNI
- Non-standard ports via cloud load-balancers, external IP, and NodePort

Routes vs Ingress

Feature	Ingress	Route
Standard Kubernetes object	X	
External access to services	X	X
Persistent (sticky) sessions	X	X
Load-balancing strategies (e.g. round robin)	X	X
Rate-limit and throttling	X	X
IP whitelisting	X	X
TLS edge termination	X	X
TLS re-encryption	X	X
TLS passthrough	X	X
Multiple weighted backends (split traffic)		X
Generated pattern-based hostnames		X
Wildcard domains		X

Router-based deployment methodologies

Split Traffic Between
Multiple Services For A/B
Testing, Blue/Green and
Canary Deployments

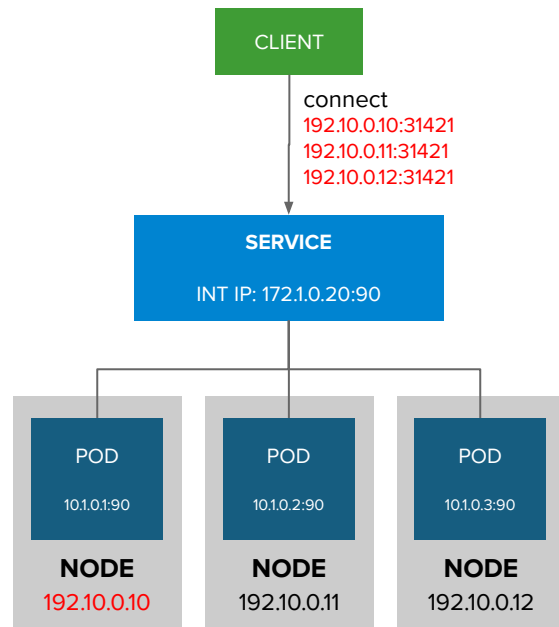

Alternative methods for ingress

Different ways that traffic can enter the cluster without the router

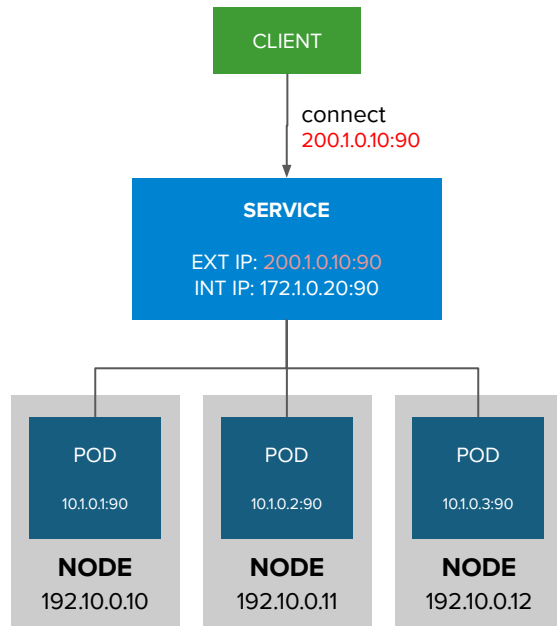

Entering the cluster on a random port with service nodeports

- NodePort binds a service to a unique port on all the nodes
- Traffic received on any node redirects to a node with the running service
- Ports in 30K-60K range which usually differs from the service
- Firewall rules must allow traffic to all nodes on the specific port

External traffic to a service on any port with external IP

- Access a service with an external IP on any TCP/UDP port, such as
 - Databases
 - Message Brokers
- Automatic IP allocation from a predefined pool using Ingress IP Self-Service
- IP failover pods provide high availability for the IP pool (fully supported in 4.8)

Cluster DNS

An automated system
for providing hostname
resolution within
kubernetes

CoreDNS

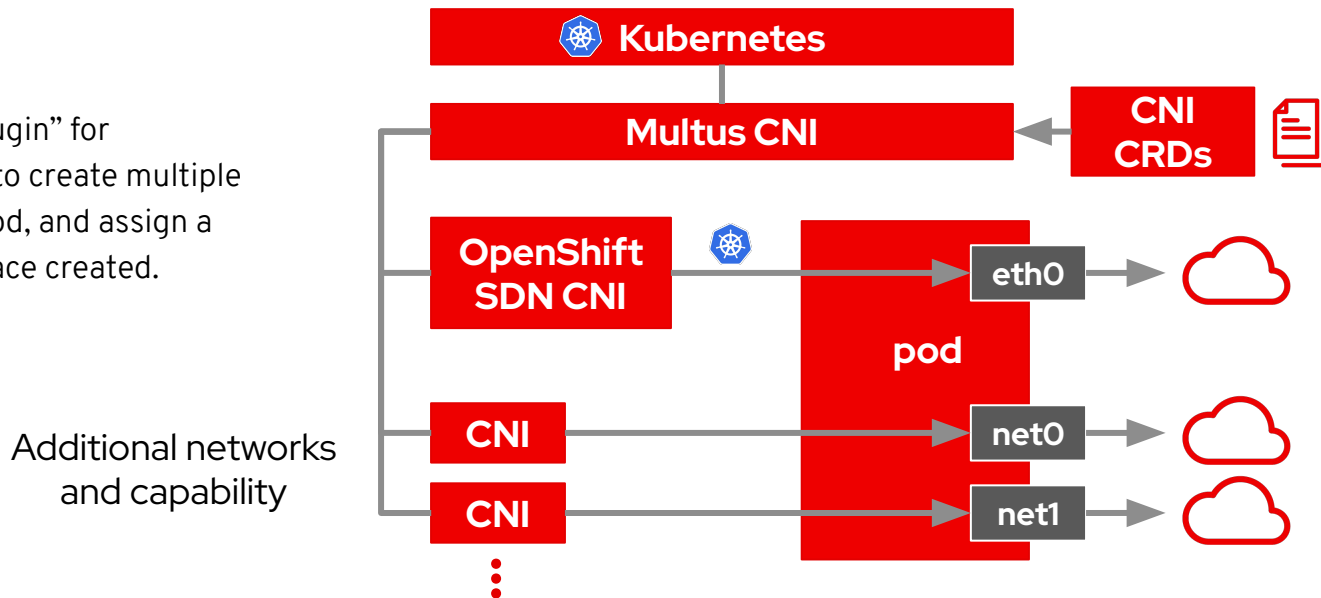

- Built-in internal DNS to reach services by a (fully qualified) hostname
- Split DNS is used with CoreDNS
 - CoreDNS answers DNS queries for internal/cluster services
 - Other defined “upstream” name servers serve the rest of the queries

Multus

A CNI plugin that
provides multiple
network interfaces for
pods

Multinetwork with Multus

The Multus CNI “meta plugin” for Kubernetes enables one to create multiple network interfaces per pod, and assign a CNI plugin to each interface created.

Additional OpenShift-Supported Secondary CNI Plug-Ins

OpenShift 4.x Tested Integrations: [Network Components and Plugins](#)

- host device
- IPAM(dhcp)
- MACVLAN
- IPVLAN
- Bridge with VLAN
- Static IPAM
- DHCP IPAM
- Route Override
- whereabouts
- SR-IOV
- ...

SR-IOV

High-performance multicast

OpenShift Monitoring

An integrated cluster
monitoring and alerting
stack

OpenShift Cluster Monitoring

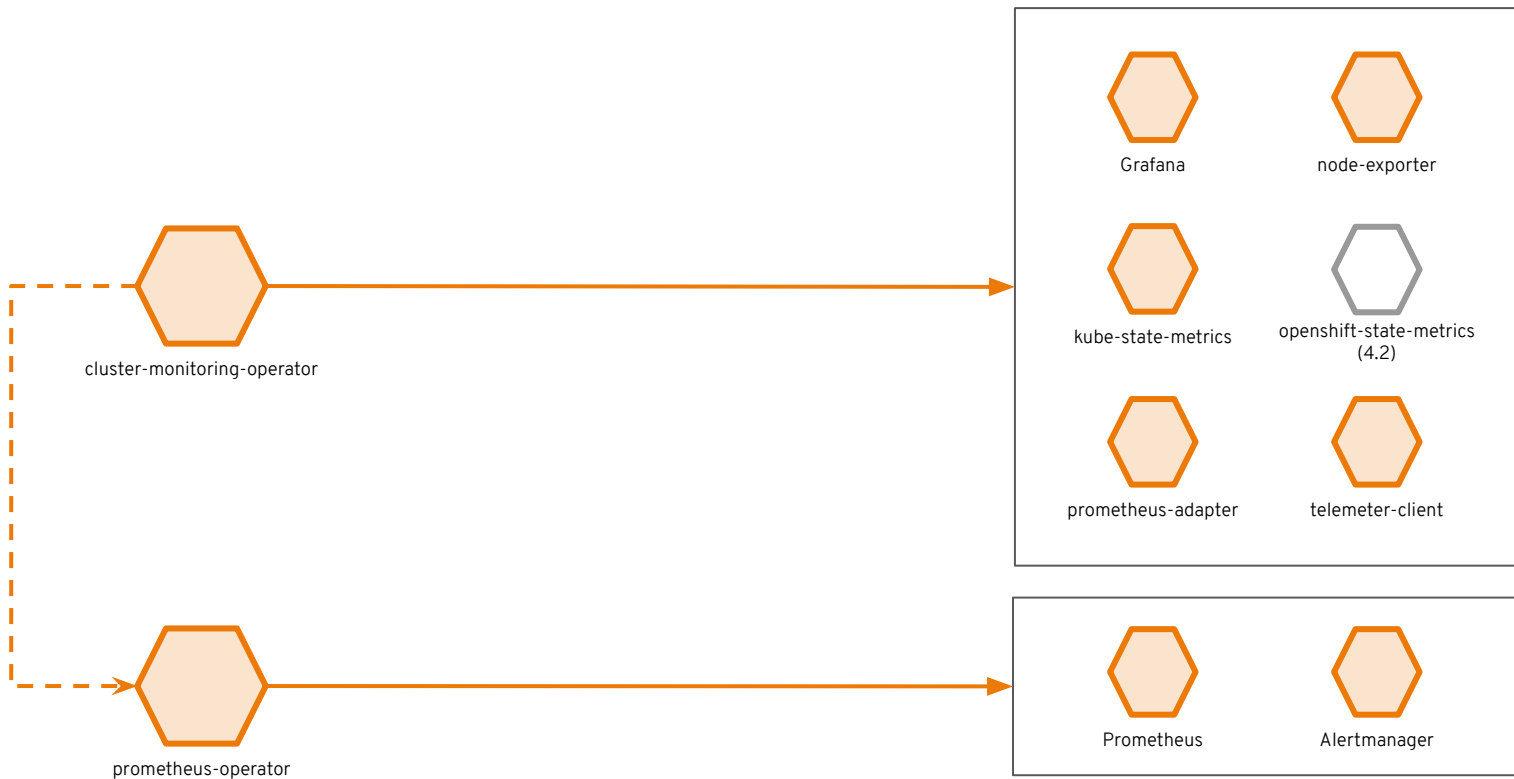

Metrics collection and storage
via Prometheus, an
open-source monitoring system
time series database.

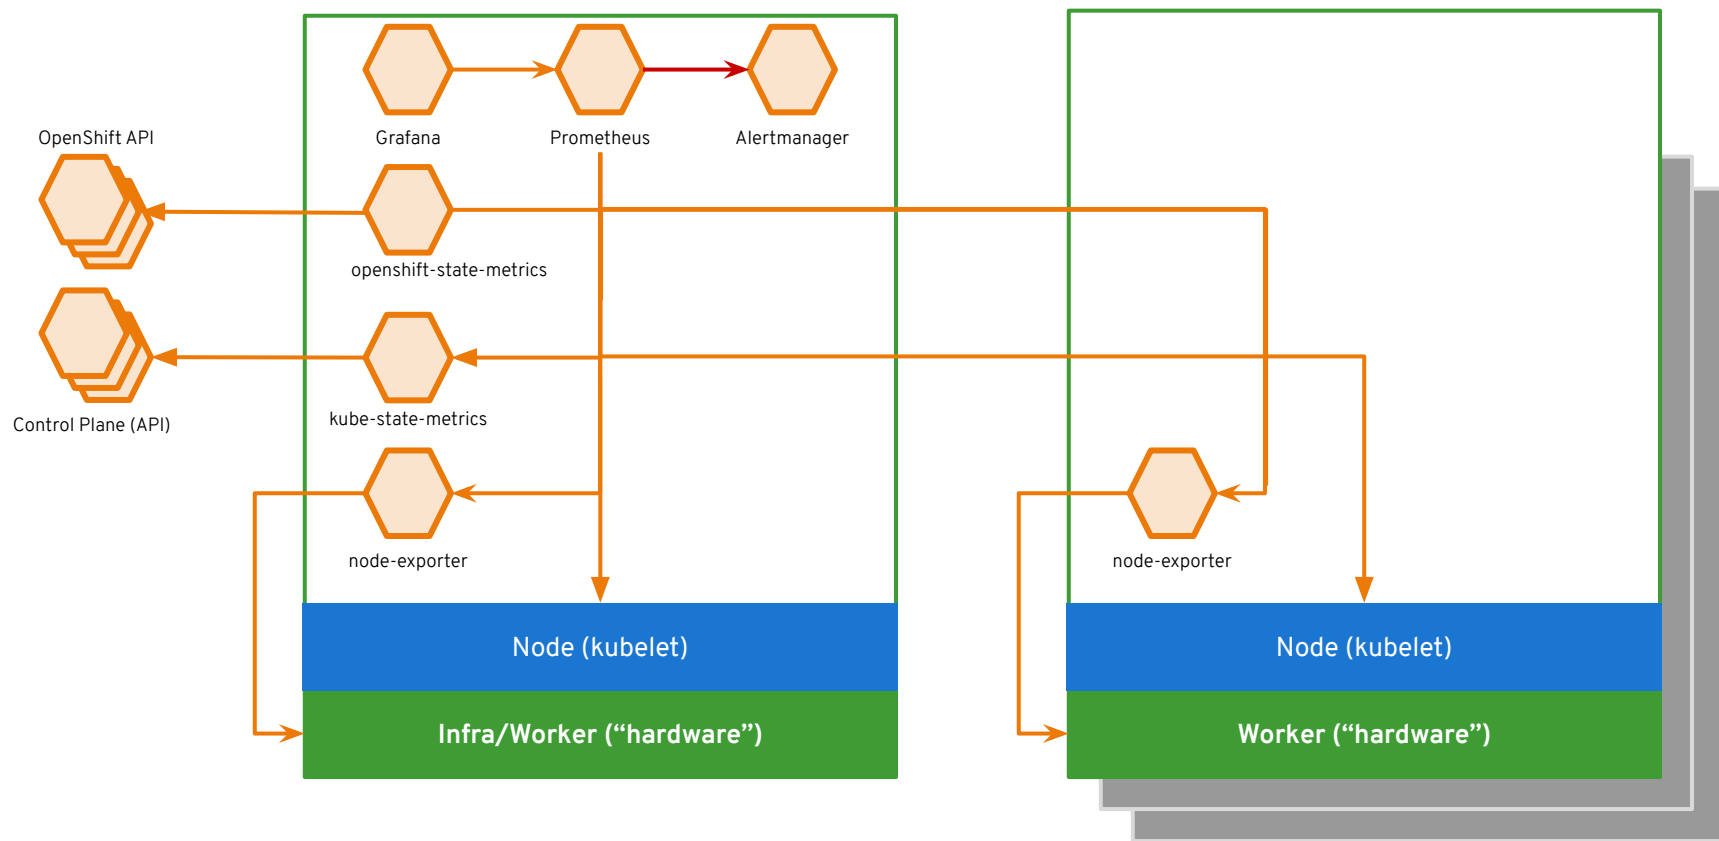

Alerting/notification via
Prometheus' Alertmanager, an
open-source tool that handles
alerts send by Prometheus.

Metrics visualization via
Grafana, the leading metrics
visualization technology.

OpenShift Logging

An integrated solution
for exploring and
corroborating
application logs

Observability via log exploration and corroboration with EFK

Components

- **Elasticsearch:** a search and analytics engine to store logs
- **Fluentd:** gathers logs and sends to Elasticsearch.
- **Kibana:** A web UI for Elasticsearch.

Access control

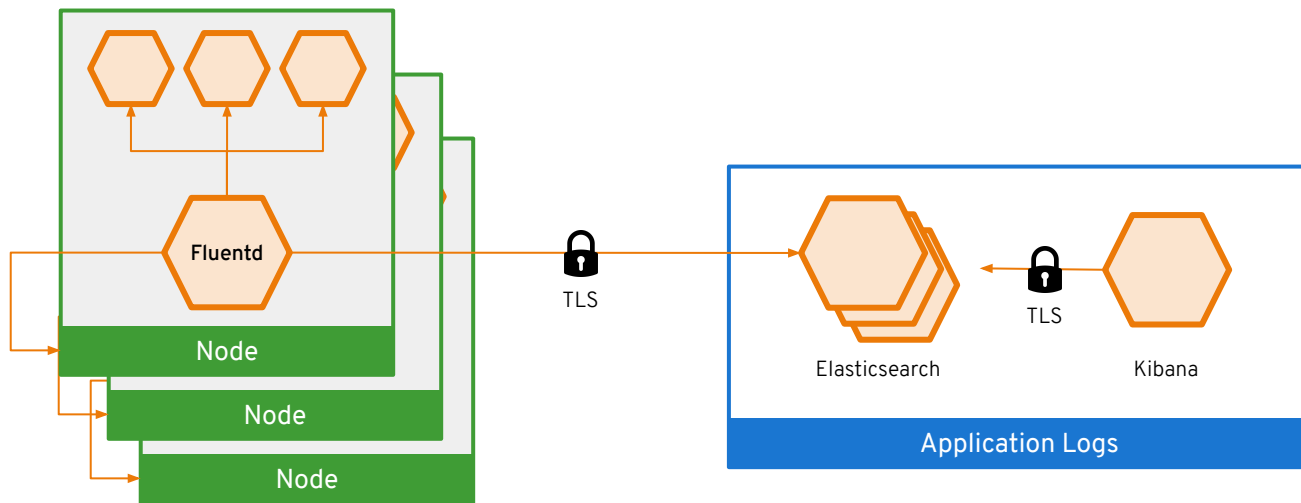

- Cluster administrators can view all logs
- Users can only view logs for their projects

Ability to forward logs elsewhere

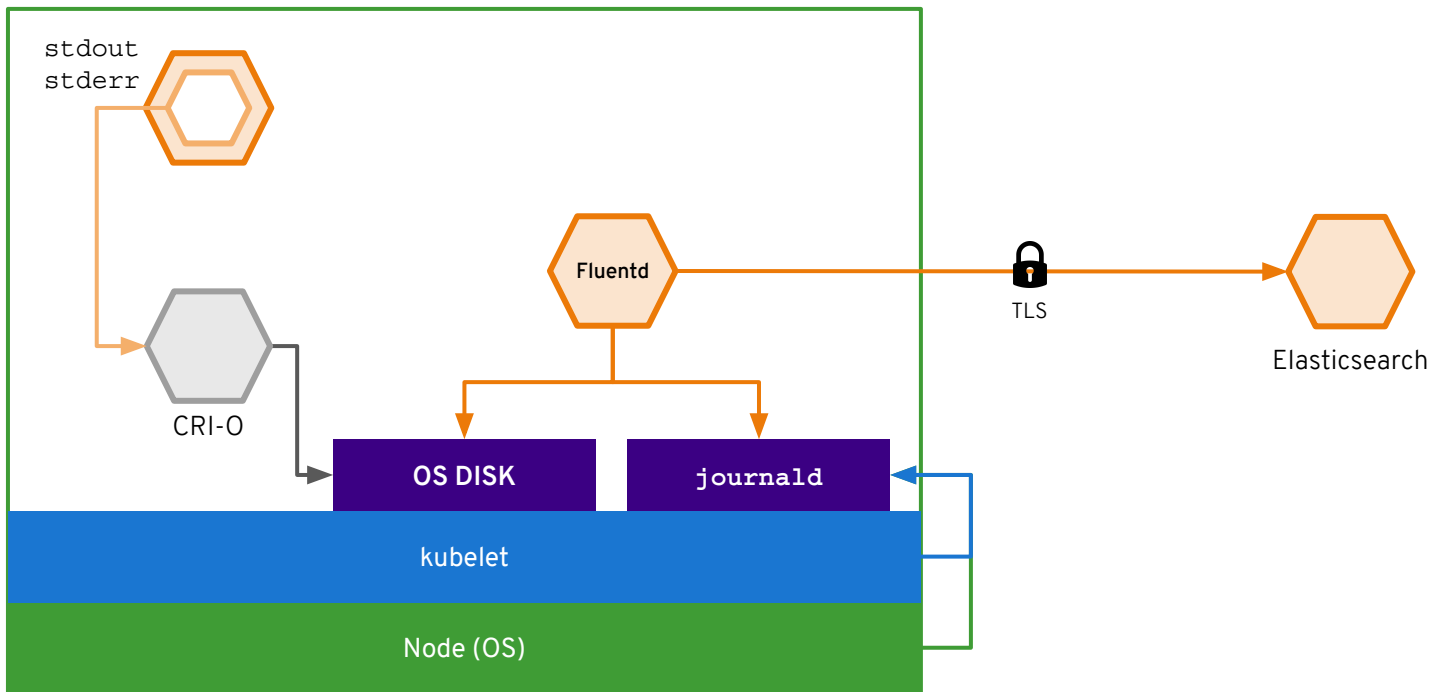

- External elasticsearch, Splunk, etc

Log data flow in OpenShift

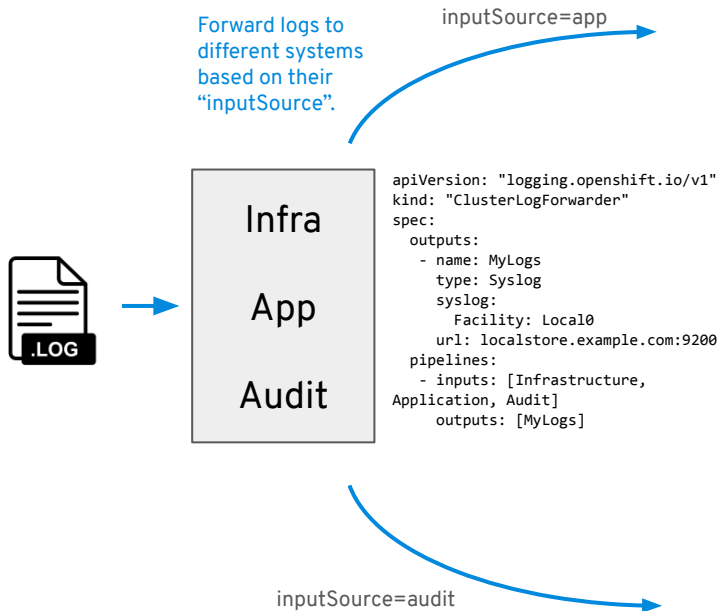

Log data flow in OpenShift

New log forwarding API (since 4.6)

Abstract Fluentd configuration by introducing new log forwarding API to improve support and experience for customers.

- Introducing a new, cluster-wide *ClusterLogForwarder* CRD (API) that replaces needs to configure log forwarding via Fluentd ConfigMap.
- The API helps to reduce probability to misconfigure Fluentd and helps bringing in more stability into the Logging stack.
- Features include: Audit log collection and forwarding, Kafka support, namespace- and source-based routing, tagging, as well as improvements to the existing log forwarding features (e.g. syslog RFC5424 support).

Secure Log Forwarding to 3rd party

```
apiVersion: "logging.openshift.io/v1"
kind: "ClusterLogForwarder"
spec:
  outputs:
    - name: MyLogs
      type: Syslog
      syslog:
        Facility: Local0
        url: localstore.example.com:9200
  pipelines:
    - inputs: [Infrastructure,
      Application, Audit]
      outputs: [MyLogs]
```

Persistent Storage

Connecting real-world
storage to your
containers to enable
stateful applications

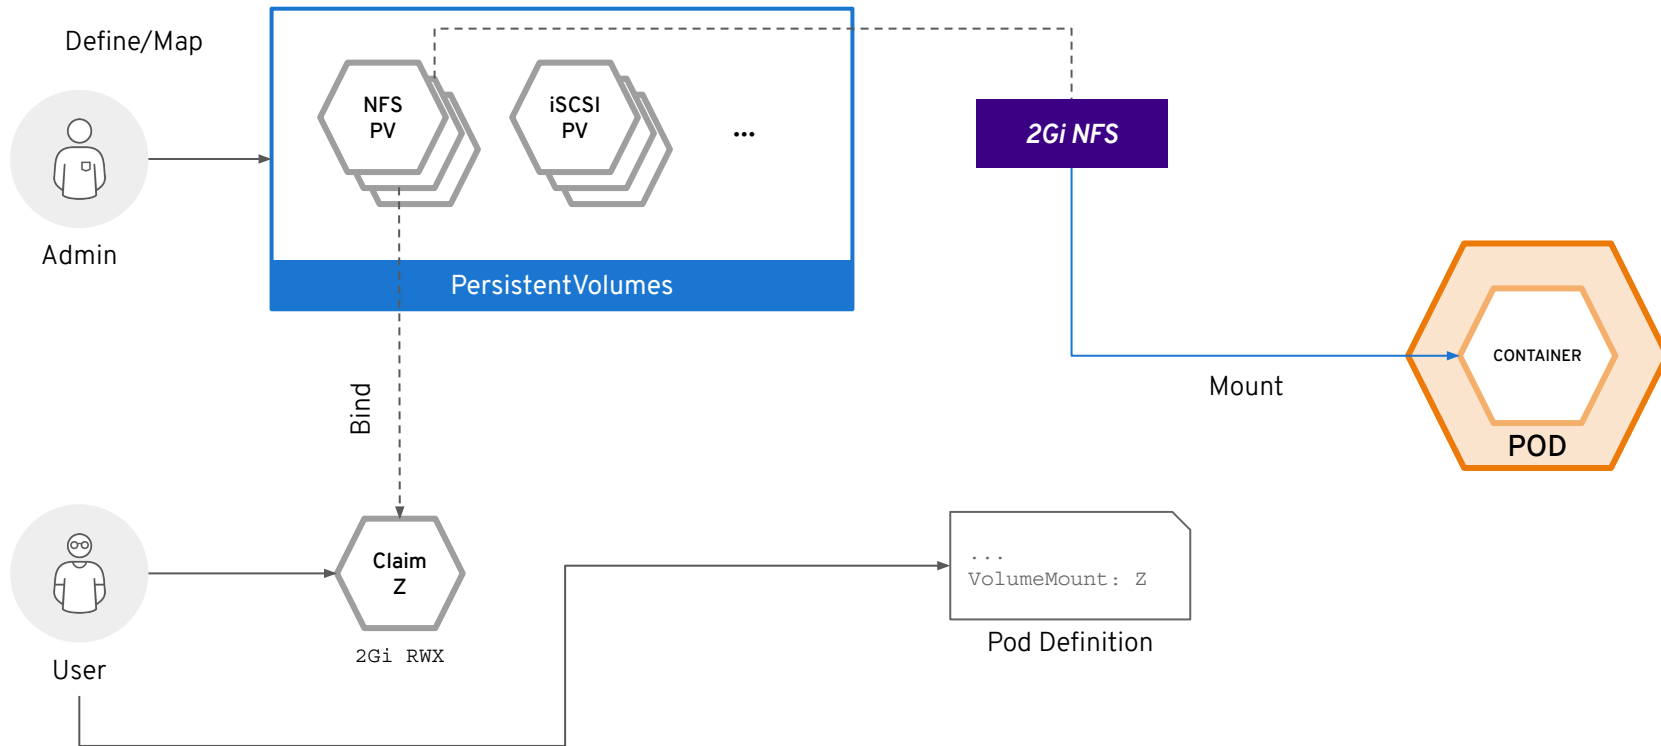

A broad spectrum of static and dynamic storage endpoints

PV Consumption

Static Storage Provisioning

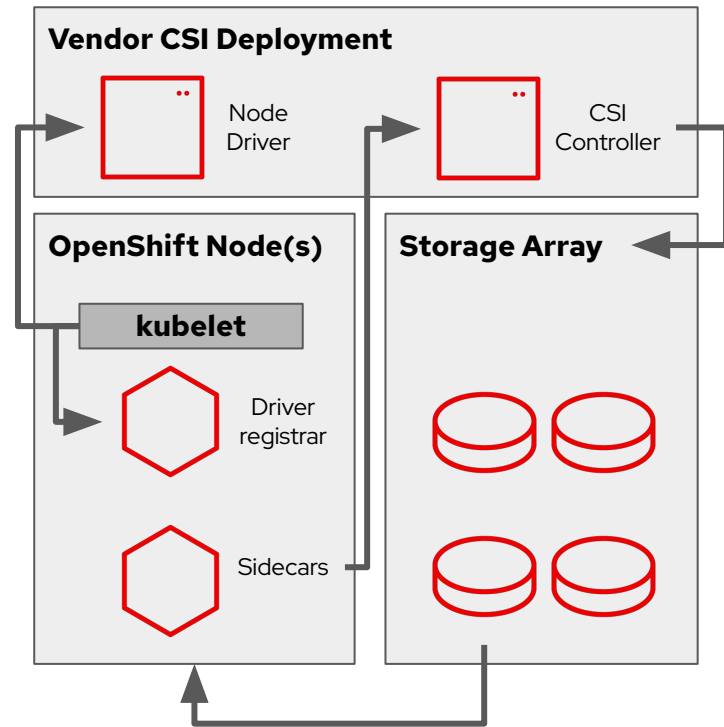

Dynamic Storage Provisioning

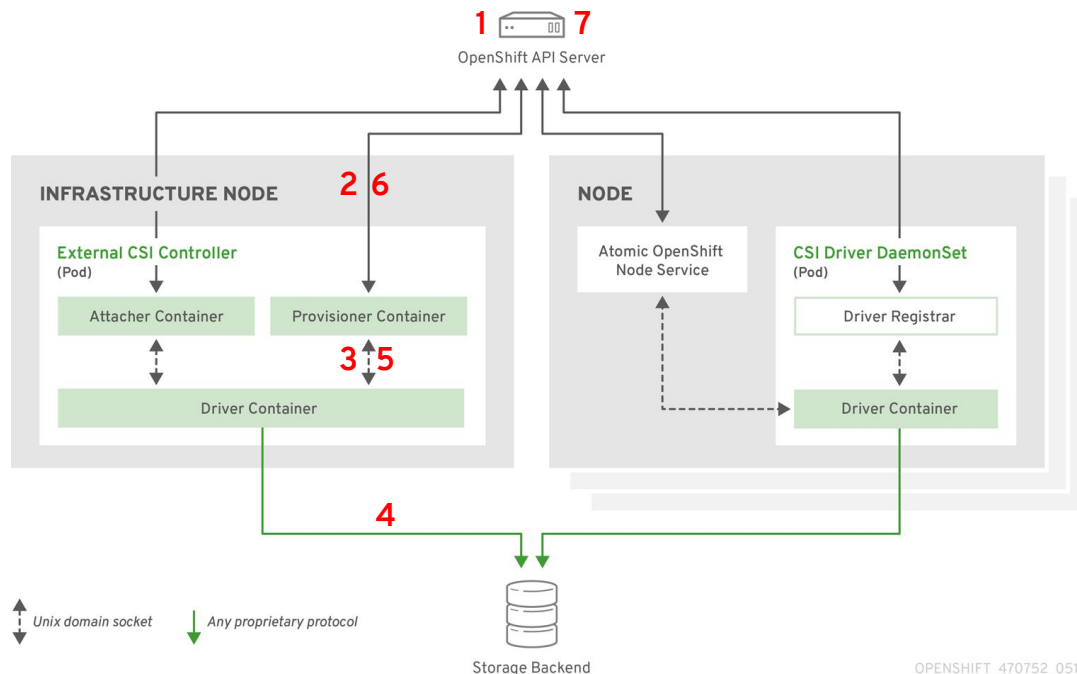

CSI Driver Paradigm

- CSI drivers and logic are provided by storage vendors
 - Each implementation may be different based on the vendor
- Controller logic is deployed to the OpenShift cluster as an Operator, deployment, or even a standalone Pod(s)
 - Responsible for interfacing with storage device to create and manage volumes, snapshots, clones, etc.
 - Respond to events (create, delete PVC) for assigned StorageClass(es)
 - Sidecars assist with hooks for additional functionality - snapshots, resizing, etc.
- Each node hosts, via a DaemonSet, one or more CSI node plugin Pods for the driver
 - Kubelet requests the node plugin to mount/unmount volumes, format block devices if needed, etc.

CSI Dynamic Provisioning

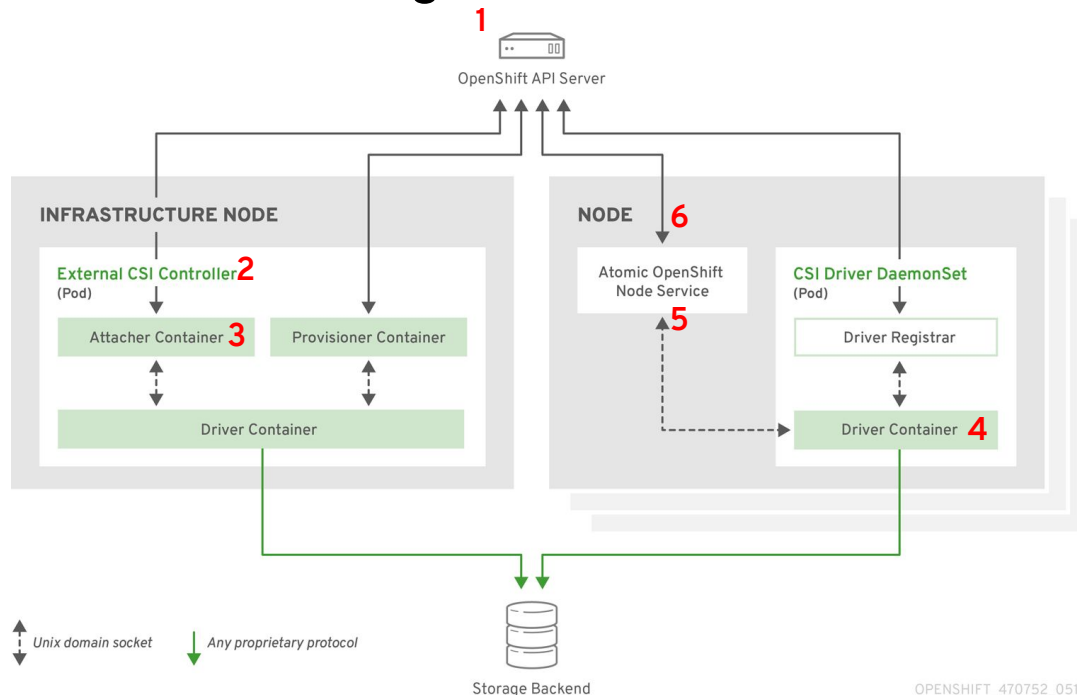

1. User creates a PVC
2. The external provisioner gets an event that a new PVC was created
3. The external provisioner initiates CreateVolume call to the CSI driver
4. The CSI driver talks to storage backend and creates a volume
5. The CSI driver returns a volume to the external provisioner
6. The external provisioner creates PV on API server
7. Kubernetes PV controller finishes the binding (PVC is Bound)

OPENSIFT_470752_0518

CSI Volume Mounting

1. User instantiates a Pod with a PVC
2. The CSI controller is notified of a volume publish event via the attacher sidecar
3. The CSI controller takes any actions on the storage device to make the volume mountable, e.g. NFS export rules
4. The node driver stages the volume, taking action to prepare the volume to be used, e.g. formatting a non-raw block device
5. The node driver mounts the volume at the location requested by Kubelet
6. The volume is attached to the container, by Kubelet, as defined

OPENSHIFT_470752_0518

Developer Experience

Application Probes

Improving reliability
and availability of
applications via built-in
probes

Three Types: One Goal

Liveness Probes

Readiness Probes

Important settings

`initialDelaySeconds`: How long to wait after the pod is launched to begin checking

`timeoutSeconds`: How long to wait for a successful connection (httpGet, tcpSocket only)

`periodSeconds`: How frequently to recheck

`failureThreshold`: How many consecutive failed checks before the probe is considered failed

Build and Deploy Container Images

Tools and automation
that makes developers
productive quickly
